Executive Summary

This workbook is intended to provide all necessary details and information for a developer to understand and remediate the different issues discovered during the scan_results project audit. The information contained in this workbook is targeted at project managers and developers.

This section provides an overview of the issues uncovered during analysis.

Project Name:	scan_results
Project Version:	
SCA:	Results Present
WebInspect:	Results Not Present
WebInspect Agent:	Results Not Present

Results Outline

Access Control: SecurityManager Bypass (5 issues)

Abstract

Invoking this function on untrusted code can allow attackers to access restricted packages and the ability to execute arbitrary code.

Explanation

Java APIs that perform tasks using the immediate caller's class loader check should be used with caution. These APIs bypass the SecurityManager check that ensures all callers in the execution chain have been granted the requisite security permission. These APIs should not be invoked on behalf of untrusted code, as they may compromise system security. In this case, : 1. The enclosing function is reachable via a public function. 2. The current application has a Process Control and/or Unsafe JNI(Java Native Interface) vulnerability. These two findings imply the current application loads a library from an untrusted source or in an untrusted environment. The untrusted library can use JNI to access this vulnerable API to get access to restricted packages and execute arbitrary code making the application vulnerable to remote attacks. Note: This finding is only applicable if the application is configured with a SecurityManager and the code is enclosed within a privileged class. Please refer to Guideline 9 of The Secure Coding Guidelines for the Java Programming Language, for further details on SecurityManager and this vulnerability.

Recommendation

Ensure that these sensitive APIs are not reachable by untrusted code and cannot be invoked on behalf of untrusted code. Also, do not propagate objects returned from this method back to untrusted code. Please refer to Guideline 9 of The Secure Coding Guidelines for the Java Programming Language, for further details on this vulnerability.

Access Specifier Manipulation (2 issues)

Abstract

The method call changes an access specifier.

Explanation

The AccessibleObject API allows the programmer to get around the access control checks provided by Java access specifiers. In particular it enables the programmer to allow a reflected object to bypass Java access controls and in turn change the value of private fields or invoke private methods, behaviors that are normally disallowed.

Recommendation

Access specifiers should only be changed by a privileged class using arguments that an attacker cannot set. All occurrences should be examined carefully.

Code Correctness: Byte Array to String Conversion (3 issues)

Abstract

Converting a byte array into a `String` may lead to data loss.

Explanation

When data from a byte array is converted into a `String`, it is unspecified what will happen to any data that is outside of the applicable character set. This can lead to data being lost, or a decrease in the level of security when binary data is needed to ensure proper security measures are followed. **Example 1:** The following code converts data into a `String` in order to create a hash.

```
...
FileInputStream fis = new FileInputStream(myFile);
byte[] byteArr = new byte[BUFSIZE];
...
int count = fis.read(byteArr);
...
String fileString = new String(byteArr);
String fileSHA256Hex = DigestUtils.sha256Hex(fileString);
// use fileSHA256Hex to validate file
...
```

Assuming the size of the file is less than `BUFSIZE`, this works fine as long as the information in `myFile` is encoded the same as the default character set, however if it's using a different encoding, or is a binary file, it will lose information. This in turn will cause the resulting SHA hash to be less reliable, and could mean it's far easier to cause collisions, especially if any data outside of the default character set is represented by the same value, such as a question mark.

Recommendation

Generally speaking, a byte array potentially containing noncharacter data should never be converted into a `String` object as it may break functionality, but in some cases this can cause much larger security concerns. In a lot of cases there is no need to actually convert a byte array into a `String`, but if there is a specific reason to be able to create a `String` object from binary data, it must first be encoded in a way such that it will fit into the default character set.

Example 2: The following uses a different variant of the API in `Example 1` to prevent any validation problems.

```
...
FileInputStream fis = new FileInputStream(myFile);
byte[] byteArr = new byte[BUFSIZE];
...
int count = fis.read(byteArr);
...
byte[] fileSHA256 = DigestUtils.sha256(byteArr);
// use fileSHA256 to validate file, comparing hash byte-by-byte.
...
```

In this case, it is straightforward to rectify, since this API has overloaded variants including one that accepts a byte array, and this could be simplified even further by using another overloaded variant of `DigestUtils.sha256()` that accepts a `FileInputStream` object as its argument. Other scenarios may need careful consideration as to whether it's possible that the byte array could contain data outside of the character set, and further refactoring may be required.

103 Packet packet = null;

```

Code Correctness: Call to notify() (13 issues)

Abstract

It is ambiguous which thread will wake up when `notify()` is called.

Explanation

There is no way to specify which thread will be awakened by calls to `notify()`. **Example 1:** In the following code, `notifyJob()` calls `notify()`.

```
public synchronized notifyJob() {
    flag = true;
    notify();
}

...
public synchronized waitForSomething() {
    while(!flag) {
        try {
            wait();
        }
        catch (InterruptedException e)
        {
            ...
        }
    }
}

...
}
```

In this case, the developer intends to wake up the thread that calls `wait()`, but it is possible that `notify()` will notify a different thread than the intended one. This category was derived from the Cigital Java Rulepack.

Recommendation

Use `notifyAll()` instead of `notify()`. Unless your applications is highly parallel and each thread performs similar actions, you should not use `notify()`. **Example 2:** In the following code, `notifyJob()` calls `notifyAll()`.

```
public synchronized notifyJob() {
    flag = true;
    notify();
}

...
public synchronized waitForSomething() {
    while(!flag) {
        try {
            wait();
        }
        catch (InterruptedException e)
        {
            ...
        }
    }
}

...
}
```

Here, the call to `notifyAll()` ensures the thread that called `wait()` will be notified.

Code Correctness: Constructor Invokes Overridable Function (16 issues)

Abstract

A constructor of the class calls a function that can be overridden.

Explanation

When a constructor calls an overridable function, it may allow an attacker to access the `this` reference prior to the object being fully initialized, which can in turn lead to a vulnerability. **Example 1:** The following calls a method that can be overridden.

```
...
class User {
    private String username;
    private boolean valid;
    public User(String username, String password){
        this.username = username;
        this.valid = validateUser(username, password);
    }
    public boolean validateUser(String username, String password){
        //validate user is real and can authenticate
        ...
    }
    public final boolean isValid(){
        return valid;
    }
}
```

Since the function `validateUser` and the class are not `final`, it means that they can be overridden, and then initializing a variable to the subclass that overrides this function would allow bypassing of the `validateUser` functionality. For example:

```
...
class Attacker extends User{
    public Attacker(String username, String password){
        super(username, password);
    }
    public boolean validateUser(String username, String password){
        return true;
    }
}
...
class MainClass{
    public static void main(String[] args){
        User hacker = new Attacker("Evil", "Hacker");
        if (hacker.isValid()){
            System.out.println("Attack successful!");
        }else{
            System.out.println("Attack failed");
        }
    }
}
```

The code in Example 1 prints "Attack successful!", since the `Attacker` class overrides the `validateUser()` function that is called from the constructor of the superclass `User`, and Java will first look in the subclass for functions called from the constructor.

Recommendation

Constructors should not call functions that can be overridden, either by specifying them as `final`, or specifying the class as `final`. Alternatively if this code is only ever needed in the constructor, the `private` access specifier can be used, or the logic could be placed directly into the constructor of the superclass. **Example 2:** The following makes the class `final` to prevent the function from being overridden elsewhere.

```
...
final class User {
    private String username;
    private boolean valid;
    public User(String username, String password){
        this.username = username;
        this.valid = validateUser(username, password);
    }
    private boolean validateUser(String username, String password){
        //validate user is real and can authenticate
        ...
    }
    public final boolean isValid(){
        return valid;
    }
}
```

This example specifies the class as `final`, so that it cannot be subclassed, and changes the `validateUser()` function to `private`, since it is not needed elsewhere in this application. This is programming defensively, since at a later date it may be decided that the `User` class needs to be subclassed, which would result in this vulnerability reappearing if the `validateUser()` function was not set to `private`.

Denial of Service (16 issues)

Abstract

An attacker could cause the program to crash or otherwise become unavailable to legitimate users.

Explanation

Attackers may be able to deny service to legitimate users by flooding the application with requests, but flooding attacks can often be defused at the network layer. More problematic are bugs that allow an attacker to overload the application using a small number of requests. Such bugs allow the attacker to specify the quantity of system resources their requests will consume or the duration for which they will use them. **Example 1:** The following code allows a user to specify the amount of time for which a thread will sleep. By specifying a large number, an attacker may tie up the thread indefinitely. With a small number of requests, the attacker may deplete the application's thread pool.

```
int usrSleepTime = Integer.parseInt(usrInput);
Thread.sleep(usrSleepTime);
```

Example 2: The following code reads a String from a zip file. Because it uses the `readLine()` method, it will read an unbounded amount of input. An attacker may take advantage of this code to cause an `OutOfMemoryException` or to consume a large amount of memory so that the program spends more time performing garbage collection or runs out of memory during some subsequent operation.

```
InputStream zipInput = zipFile.getInputStream(zipEntry);
Reader zipReader = new InputStreamReader(zipInput);
BufferedReader br = new BufferedReader(zipReader);
String line = br.readLine();
```

Recommendation

Validate user input to ensure that it will not cause inappropriate resource utilization. **Example 3:** The following code allows a user to specify the amount of time for which a thread will sleep just as in Example 1, but only if the value is within reasonable bounds.

```
int usrSleepTime = Integer.parseInt(usrInput);
if (usrSleepTime >= SLEEP_MIN &&
    usrSleepTime <= SLEEP_MAX) {
    Thread.sleep(usrSleepTime);
} else {
    throw new Exception("Invalid sleep duration");
}
}
```

Example 4: The following code reads a String from a zip file just as in Example 2, but the maximum string length it will read is `MAX_STR_LEN` characters.

```
InputStream zipInput = zipFile.getInputStream(zipEntry);
Reader zipReader = new InputStreamReader(zipInput);
BufferedReader br = new BufferedReader(zipReader);
StringBuffer sb = new StringBuffer();
int intC;
while ((intC = br.read()) != -1) {
    char c = (char) intC;
    if (c == '\n') {
        break;
    }
    if (sb.length() >= MAX_STR_LEN) {
        throw new Exception("input too long");
    }
    sb.append(c);
}
```

```
String line = sb.toString();
```

Insecure Randomness (11 issues)

Abstract

Standard pseudorandom number generators cannot withstand cryptographic attacks.

Explanation

Insecure randomness errors occur when a function that can produce predictable values is used as a source of randomness in a security-sensitive context. Computers are deterministic machines, and as such are unable to produce true randomness. Pseudorandom Number Generators (PRNGs) approximate randomness algorithmically, starting with a seed from which subsequent values are calculated. There are two types of PRNGs: statistical and cryptographic. Statistical PRNGs provide useful statistical properties, but their output is highly predictable and form an easy to reproduce numeric stream that is unsuitable for use in cases where security depends on generated values being unpredictable. Cryptographic PRNGs address this problem by generating output that is more difficult to predict. For a value to be cryptographically secure, it must be impossible or highly improbable for an attacker to distinguish between the generated random value and a truly random value. In general, if a PRNG algorithm is not advertised as being cryptographically secure, then it is probably a statistical PRNG and should not be used in security-sensitive contexts, where its use can lead to serious vulnerabilities such as easy-to-guess temporary passwords, predictable cryptographic keys, session hijacking, and DNS spoofing. **Example 1:** The following code uses a statistical PRNG to create a URL for a receipt that remains active for some period of time after a purchase.

```
String GenerateReceiptURL(String baseUrl) {  
    Random ranGen = new Random();  
    ranGen.setSeed((new Date()).getTime());  
    return (baseUrl + ranGen.nextInt(400000000) + ".html");  
}
```

This code uses the `Random.nextInt()` function to generate "unique" identifiers for the receipt pages it generates. Since `Random.nextInt()` is a statistical PRNG, it is easy for an attacker to guess the strings it generates. Although the underlying design of the receipt system is also faulty, it would be more secure if it used a random number generator that did not produce predictable receipt identifiers, such as a cryptographic PRNG.

Recommendation

When unpredictability is critical, as is the case with most security-sensitive uses of randomness, use a cryptographic PRNG. Regardless of the PRNG you choose, always use a value with sufficient entropy to seed the algorithm. (Do not use values such as the current time because it offers only negligible entropy.) The Java language provides a cryptographic PRNG in `java.security.SecureRandom`. As is the case with other algorithm-based classes in `java.security`, `SecureRandom` provides an implementation-independent wrapper around a particular set of algorithms. When you request an instance of a `SecureRandom` object using `SecureRandom.getInstance()`, you can request a specific implementation of the algorithm. If the algorithm is available, then it is given as a `SecureRandom` object. If it is unavailable or if you do not specify a particular implementation, then you are given a `SecureRandom` implementation selected by the system. Sun provides a single `SecureRandom` implementation with the Java distribution named `SHA1PRNG`, which Sun describes as computing: "The SHA-1 hash over a true-random seed value concatenated with a 64-bit counter which is incremented by 1 for each operation. From the 160-bit SHA-1 output, only 64 bits are used [1]." However, the specifics of the Sun implementation of the `SHA1PRNG` algorithm are poorly documented, and it is unclear what sources of entropy the implementation uses and therefore what amount of true randomness exists in its output. Although there is speculation on the Web about the Sun implementation, there is no evidence to contradict the claim that the algorithm is cryptographically strong and can be used safely in security-sensitive contexts.

J2EE Bad Practices: Leftover Debug Code (1 issue)

Abstract

Debug code can create unintended entry points in a deployed web application.

Explanation

A common development practice is to add "back door" code specifically designed for debugging or testing purposes that is not intended to be shipped or deployed with the application. When this sort of debug code is accidentally left in the application, the application is open to unintended modes of interaction. These back door entry points create security risks because they are not considered during design or testing and fall outside of the expected operating conditions of the application. The most common example of forgotten debug code is a `main()` method appearing in a web application. Although this is an acceptable practice during product development, classes that are part of a production J2EE application should not define a `main()`.

Recommendation

Remove debug code before deploying a production version of an application. Regardless of whether a direct security threat can be articulated, it is unlikely that there is a legitimate reason for such code to remain in the application after the early stages of development.

Issue Summary

J2EE Bad Practices: Threads (65 issues)

Abstract

Thread management in a web application is forbidden in some circumstances and is always highly error prone.

Explanation

Thread management in a web application is forbidden by the J2EE standard in some circumstances and is always highly error prone. Managing threads is difficult and is likely to interfere in unpredictable ways with the behavior of the application container. Even without interfering with the container, thread management usually leads to bugs that are hard to detect and diagnose like deadlock, race conditions, and other synchronization errors.

Recommendation

Avoid managing threads directly from within the web application. Instead use standards such as message driven beans and the EJB timer service that are provided by the application container.

Missing XML Validation (4 issues)

Abstract

Failure to enable validation when parsing XML gives an attacker the opportunity to supply malicious input.

Explanation

Most successful attacks begin with a violation of the programmer's assumptions. By accepting an XML document without validating it against a DTD or XML schema, the programmer leaves a door open for attackers to provide unexpected, unreasonable, or malicious input. It is not possible for an XML parser to validate all aspects of a document's content; a parser cannot understand the complete semantics of the data. However, a parser can do a complete and thorough job of checking the document's structure and therefore guarantee to the code that processes the document that the content is well-formed.

Recommendation

Always enable validation when you create an XML parser or parser factory. If enabling validation causes problems because the rules for defining a well-formed document are Byzantine or altogether unknown, chances are good that there are security errors nearby. The following examples demonstrate how to enable validation for the Xerces parsers (both DOM and SAX):

```
org.apache.xerces.framework.XMLParser: parser.setValidation(true);
org.apache.xerces.framework.XMLParser: parser.setValidationSchema(true);
```

The following examples demonstrate how to enable validation for the SAX and DOM parser factories in the javax library. javax SAX parser factory:

```
javax.xml.parsers.SAXParserFactory: factory.setValidating(true);
javax.xml.parsers.SAXParserFactory: factory.setFeature("http://xml.org/sax/features/validation", true);
```

javax DOM parser factory:

```
javax.xml.parsers.DocumentBuilderFactory: factory.setValidating(true);
```

The following examples demonstrate how to enable validation for individual parsers and XMLReaders in the javax library. Note: The Fortify Software Security Research group does not recommend enabling validation by this method.

Instead, you should enable validation at the parser factory. javax SAX parser and reader:

```
javax.xml.parsers.SAXParser: parser.setProperty("http://xml.org/sax/features/validation", new Boolean(true));
org.xml.sax.XMLReader: reader.setFeature("http://xml.org/sax/features/validation", true);
```

The following examples demonstrate how to set the XML return type for Apache Axis. Axis client Call:

```
call.addParameter("testParam", org.apache.axis.Constants.XSD_STRING,
    javax.xml.rpc.ParameterMode.IN);
call.setReturnType(org.apache.axis.Constants.XSD_STRING);
String ret = (String) call.invoke( new Object[] { "Hello!" } );
```

Null Dereference (1 issue)

Abstract

The program can potentially dereference a null-pointer, thereby causing a null-pointer exception.

Explanation

Null-pointer exceptions usually occur when one or more of the programmer's assumptions is violated. A dereference-after-store error occurs when a program explicitly sets an object to `null` and dereferences it later. This error is often the result of a programmer initializing a variable to `null` when it is declared. Most null-pointer issues result in general software reliability problems, but if attackers can intentionally trigger a null-pointer dereference, they can use the resulting exception to bypass security logic or to cause the application to reveal debugging information that will be valuable in planning subsequent attacks. **Example 1:** In the following code, the programmer explicitly sets the variable `foo` to `null`. Later, the programmer dereferences `foo` before checking the object for a `null` value.

```
Foo foo = null;
...
foo.setBar(val);
...
}
```

Recommendation

Implement careful checks before dereferencing objects that might be `null`. When possible, abstract `null` checks into wrappers around code that manipulates resources to ensure that they are applied in all cases and to minimize the places where mistakes can occur.

Often Misused: Authentication (2 issues)

Abstract

Attackers may spoof DNS entries. Do not rely on DNS names for security.

Explanation

Many DNS servers are susceptible to spoofing attacks, so you should assume that your software will someday run in an environment with a compromised DNS server. If attackers are allowed to make DNS updates (sometimes called DNS cache poisoning), they can route your network traffic through their machines or make it appear as if their IP addresses are part of your domain. Do not base the security of your system on DNS names. **Example 1:** The following code uses a DNS lookup to determine whether an inbound request is from a trusted host. If an attacker can poison the DNS cache, they can gain trusted status.

```
String ip = request.getRemoteAddr();
InetAddress addr = InetAddress.getByName(ip);
if (addr.getCanonicalHostName().endsWith("trustme.com")) {
    trusted = true;
}
```

IP addresses are more reliable than DNS names, but they can also be spoofed. Attackers may easily forge the source IP address of the packets they send, but response packets will return to the forged IP address. To see the response packets, the attacker has to sniff the traffic between the victim machine and the forged IP address. In order to accomplish the required sniffing, attackers typically attempt to locate themselves on the same subnet as the victim machine. Attackers may be able to circumvent this requirement by using source routing, but source routing is disabled across much of the Internet today. In summary, IP address verification can be a useful part of an authentication scheme, but it should not be the single factor required for authentication.

Recommendation

You can increase confidence in a domain name lookup if you check to make sure that the host's forward and backward DNS entries match. Attackers will not be able to spoof both the forward and the reverse DNS entries without controlling the nameservers for the target domain. This is not a foolproof approach however: attackers may be able to convince the domain registrar to turn over the domain to a malicious nameserver. Basing authentication on DNS entries is simply a risky proposition. While no authentication mechanism is foolproof, there are better alternatives than host-based authentication. Password systems offer decent security, but are susceptible to bad password choices, insecure password transmission, and bad password management. A cryptographic scheme like SSL is worth considering, but such schemes are often so complex that they bring with them the risk of significant implementation errors, and key material can always be stolen. In many situations, multi-factor authentication including a physical token offers the most security available at a reasonable price.

Password Management: Password in Comment (1 issue)

Abstract

Storing passwords or password details in plain text anywhere in the system or system code might compromise system security in a way that is not easy to remedy.

Explanation

It is never a good idea to hardcode a password. Storing password details within comments is equivalent to hardcoding passwords. Not only is the password visible to the project's developers, it also makes fixing the problem extremely difficult. After the code is in production, the password is now leaked to the outside world and cannot be protected or changed without patching the software. If the account protected by the password is compromised, the owners of the system must choose between security and availability. **Example 1:** The following comment specifies the default password to connect to a database:

```
...
// Default username for database connection is "scott"
// Default password for database connection is "tiger"
...
```

This code will run successfully, but anyone who has access to it will have access to the password. An employee with access to this information can use it to break into the system.

Recommendation

Passwords should never be hardcoded and should generally be obfuscated and managed in an external source. Storing passwords in plain text anywhere on the system allows anyone with sufficient permissions to read and potentially misuse the password.

Poor Error Handling: Empty Catch Block (41 issues)

Abstract

Ignoring an exception can cause the program to overlook unexpected states and conditions.

Explanation

Just about every serious attack on a software system begins with the violation of a programmer's assumptions. After the attack, the programmer's assumptions seem flimsy and poorly founded, but before an attack many programmers would defend their assumptions well past the end of their lunch break. Two dubious assumptions that are easy to spot in code are "this method call can never fail" and "it doesn't matter if this call fails". When a programmer ignores an exception, they implicitly state that they are operating under one of these assumptions. **Example 1:** The following code excerpt ignores a rarely-thrown exception from `doExchange()`.

```
try {
    doExchange();
}
catch (RareException e) {
    // this can never happen
}
```

If a `RareException` were to ever be thrown, the program would continue to execute as though nothing unusual had occurred. The program records no evidence indicating the special situation, potentially frustrating any later attempt to explain the program's behavior.

Recommendation

At a minimum, log the fact that the exception was thrown so that it will be possible to come back later and make sense of the resulting program behavior. Better yet, abort the current operation. If the exception is being ignored because the caller cannot properly handle it but the context makes it inconvenient or impossible for the caller to declare that it throws the exception itself, consider throwing a `RuntimeException` or an `Error`, both of which are unchecked exceptions. As of JDK 1.4, `RuntimeException` has a constructor that makes it easy to wrap another exception.

Example 2: The code in Example 1 could be rewritten in the following way:

```
try {
    doExchange();
}
catch (RareException e) {
    throw new RuntimeException("This can never happen", e);
}
```

Poor Error Handling: Overly Broad Catch (81 issues)

Abstract

The catch block handles a broad swath of exceptions, potentially trapping dissimilar issues or problems that should not be dealt with at this point in the program.

Explanation

Multiple catch blocks can get repetitive, but "condensing" catch blocks by catching a high-level class such as `Exception` can obscure exceptions that deserve special treatment or that should not be caught at this point in the program. Catching an overly broad exception essentially defeats the purpose of Java's typed exceptions, and can become particularly dangerous if the program grows and begins to throw new types of exceptions. The new exception types will not receive any attention. **Example 1:** The following code excerpt handles three types of exceptions in an identical fashion.

```
try {
    doExchange();
}
catch (IOException e) {
    logger.error("doExchange failed", e);
}
catch (InvocationTargetException e) {
    logger.error("doExchange failed", e);
}
catch (SQLException e) {
    logger.error("doExchange failed", e);
}
```

At first blush, it may seem preferable to deal with these exceptions in a single catch block, as follows:

```
try {
    doExchange();
}
catch (Exception e) {
    logger.error("doExchange failed", e);
}
```

However, if `doExchange()` is modified to throw a new type of exception that should be handled in some different kind of way, the broad catch block will prevent the compiler from pointing out the situation. Further, the new catch block will now also handle exceptions derived from `RuntimeException` such as `ClassCastException`, and `NullPointerException`, which is not the programmer's intent.

Recommendation

Do not catch broad exception classes such as `Exception`, `Throwable`, `Error`, or `RuntimeException` except at the very top level of the program or thread.

Poor Error Handling: Overly Broad Throws (7 issues)

Abstract

The method throws a generic exception making it harder for callers to do a good job of error handling and recovery.

Explanation

Declaring a method to throw `Exception` or `Throwable` makes it difficult for callers to do good error handling and error recovery. Java's exception mechanism is set up to make it easy for callers to anticipate what can go wrong and write code to handle each specific exceptional circumstance. Declaring that a method throws a generic form of exception defeats this system. **Example 1:** The following method throws three types of exceptions.

```
public void doExchange()  
    throws IOException, InvocationTargetException,  
           SQLException {  
    ...  
}
```

```
While it might seem tidier to write  
public void doExchange()  
    throws Exception {  
    ...  
}
```

doing so hampers the caller's ability to understand and handle the exceptions that occur. Further, if a later revision of `doExchange()` introduces a new type of exception that should be treated differently than previous exceptions, there is no easy way to enforce this requirement.

Recommendation

Do not declare methods to throw `Exception` or `Throwable`. If the exceptions thrown by a method are not recoverable or should not generally be caught by the caller, consider throwing unchecked exceptions rather than checked exceptions. This can be accomplished by implementing exception classes that extend `RuntimeException` or `Error` instead of `Exception`, or add a try/catch wrapper in your method to convert checked exceptions to unchecked exceptions.

Poor Error Handling: Program Catches NullPointerException (1 issue)

Abstract

It is generally a bad practice to catch NullPointerException.

Explanation

Programmers typically catch NullPointerException under three circumstances: 1. The program contains a null-pointer dereference. Catching the resulting exception was easier than fixing the underlying problem. 2. The program explicitly throws a NullPointerException to signal an error condition. 3. The code is part of a test harness that supplies unexpected input to the classes under test. Of these three circumstances, only the last is acceptable. **Example 1:** The following code mistakenly catches a NullPointerException.

```
try {
    mysteryMethod();
}
catch (NullPointerException npe) {
}
```

Recommendation

The program should not dereference null-pointers. If you cannot eliminate the cause of the null-pointer dereference, you must carefully review the code to make sure that the exception is handled in such a way that the program does not enter into an unexpected or illegal state. If the NullPointerException is being thrown explicitly, change the program to throw an exception derived from RuntimeException or Error instead.

Poor Error Handling: Throw Inside Finally (1 issue)

Abstract

Using a throw statement inside a finally block breaks the logical progression through the try-catch-finally.

Explanation

In Java, finally blocks are always executed after their corresponding try-catch blocks and are often used to free allocated resources, such as file handles or database cursors. Throwing an exception in a finally block can bypass critical cleanup code since normal program execution will be disrupted. **Example 1:** In the following code, the call to `stmt.close()` is bypassed when the `FileNotFoundException` is thrown.

```
public void processTransaction(Connection conn) throws FileNotFoundException
{
    FileInputStream fis = null;
    Statement stmt = null;
    try
    {
        stmt = conn.createStatement();
        fis = new FileInputStream("badFile.txt");
        ...
    }
    catch (FileNotFoundException fe)
    {
        log("File not found.");
    }
    catch (SQLException se)
    {
        //handle error
    }
    finally
    {
        if (fis == null)
        {
            throw new FileNotFoundException();
        }

        if (stmt != null)
        {
            try
            {
                stmt.close();
            }
            catch (SQLException e)
            {
                log(e);
            }
        }
    }
}
```

This category is from the Cigital Java Rulepack.

Recommendation

Never throw exceptions from within finally blocks. If you must re-throw an exception, do it inside a catch block so as not to interrupt the normal execution of the finally block. **Example 2:** The following code re-throws the

FileNotFoundException in the catch block.

```
public void processTransaction(Connection conn) throws FileNotFoundException
{
    FileInputStream fis = null;
    Statement stmt = null;
    try
    {
        stmt = conn.createStatement();
        fis = new FileInputStream("badFile.txt");
        ...
    }
    catch (FileNotFoundException fe)
    {
        log("File not found.");
        throw fe;
    }
    catch (SQLException se)
    {
        //handle error
    }
    finally
    {
        if (fis != null)
        {
            try
            {
                fis.close();
            }
            catch (IOException ie)
            {
                log(ie);
            }
        }

        if (stmt != null)
        {
            try
            {
                stmt.close();
            }
            catch (SQLException e)
            {
                log(e);
            }
        }
    }
}
```

Poor Logging Practice: Use of a System Output Stream (25 issues)

Abstract

Using `System.out` or `System.err` rather than a dedicated logging facility makes it difficult to monitor the program behavior.

Explanation

Example 1: The first Java program that a developer learns to write is the following:

```
public class MyClass
{
    ...
    System.out.println("hello world");
    ...
}
```

While most programmers go on to learn many nuances and subtleties about Java, a surprising number hang on to this first lesson and never give up on writing messages to standard output using `System.out.println()`. The problem is that writing directly to standard output or standard error is often used as an unstructured form of logging. Structured logging facilities provide features like logging levels, uniform formatting, a logger identifier, timestamps, and, perhaps most critically, the ability to direct the log messages to the right place. When the use of system output streams is jumbled together with the code that uses loggers properly, the result is often a well-kept log that is missing critical information. Developers widely accept the need for structured logging, but many continue to use system output streams in their "pre-production" development. If the code you are reviewing is past the initial phases of development, use of `System.out` or `System.err` may indicate an oversight in the move to a structured logging system.

Recommendation

Use a Java logging facility rather than `System.out` or `System.err`. **Example 2:** For example, you can rewrite the "hello world" program in Example 1 using log4j as follows:

```
import org.apache.log4j.Logger;
import org.apache.log4j.BasicConfigurator;

public class MyClass {
    private final static Logger logger =
        Logger.getLogger(MyClass.class);

    ...
    BasicConfigurator.configure();
    logger.info("hello world");
    ...
}
```

Poor Style: Non-final Public Static Field (5 issues)

Abstract

Non-final public static fields can be changed by external classes.

Explanation

Typically, you do not want to provide external classes direct access to your object's member fields since a public field can be changed by any external class. Good object oriented designed uses encapsulation to prevent implementation details, such as member fields, from being exposed to other classes. Further, if the system assumes that this field cannot be changed, then malicious code might be able to adversely change the behavior of the system. **Example 1:** In the following code, the field `ERROR_CODE` is declared as public and static, but not final:

```
public class MyClass
{
public static int ERROR_CODE = 100;
//...
}
```

In this case, malicious code might be able to change this error code and cause the program to behave in an unexpected manner. This category is from the Cigital Java Rulepack.

Recommendation

If you intend to expose a field as a constant value, the field should be declared as `public static final`, otherwise declare the field `private`. **Example 2:**

```
public class MyClass
{
public static final int ERROR_CODE = 123;
//...
}
```

Poor Style: Redundant Initialization (3 issues)

Abstract

The variable's value is assigned but never used, making it a dead store.

Explanation

This variable's initial value is not used. After initialization, the variable is either assigned another value or goes out of scope. **Example 1:** The following code excerpt assigns to the variable `r` and then overwrites the value without using it.

```
int r = getNum();
r = getNewNum(buf);
```

Recommendation

Remove unnecessary assignments in order to make the code easier to understand and maintain.

Redundant Null Check (3 issues)

Abstract

The program can dereference a null-pointer, thereby causing a null-pointer exception.

Explanation

Null-pointer exceptions usually occur when one or more of the programmer's assumptions is violated. Specifically, dereference-after-check errors occur when a program makes an explicit check for `null`, but proceeds to dereference the object when it is known to be `null`. Errors of this type are often the result of a typo or programmer oversight. Most null-pointer issues result in general software reliability problems, but if attackers can intentionally cause the program to dereference a null-pointer, they can use the resulting exception to mount a denial of service attack or to cause the application to reveal debugging information that will be valuable in planning subsequent attacks. **Example 1:** In the following code, the programmer confirms that the variable `foo` is `null` and subsequently dereferences it erroneously. If `foo` is `null` when it is checked in the `if` statement, then a `null` dereference will occur, thereby causing a null-pointer exception.

```
if (foo == null) {
    foo.setBar(val);
    ...
}
```

Recommendation

Implement careful checks before dereferencing objects that might be `null`. When possible, abstract `null` checks into wrappers around code that manipulates resources to ensure that they are applied in all cases and to minimize the places where mistakes can occur.

System Information Leak (7 issues)

Abstract

Revealing system data or debugging information helps an adversary learn about the system and form a plan of attack.

Explanation

An information leak occurs when system data or debug information leaves the program through an output stream or logging function. **Example 1:** The following code writes an exception to the standard error stream:

```
try {  
    ...  
} catch (Exception e) {  
    e.printStackTrace();  
}
```

Depending on the system configuration, this information can be dumped to a console, written to a log file, or exposed to a remote user. For example, with scripting mechanisms it is trivial to redirect output information from "Standard error" or "Standard output" into a file or another program. Alternatively, the system that the program runs on could have a remote logging mechanism such as a "syslog" server that sends the logs to a remote device. During development, you have no way of knowing where this information might end up being displayed. In some cases, the error message provides the attacker with the precise type of attack to which the system is vulnerable. For example, a database error message can reveal that the application is vulnerable to a SQL injection attack. Other error messages can reveal more oblique clues about the system. In Example 1, the leaked information could imply information about the type of operating system, the applications installed on the system, and the amount of care that the administrators have put into configuring the program. Here is another scenario, specific to the mobile world. Most mobile devices now implement a Near-Field Communication (NFC) protocol for quickly sharing information between devices using radio communication. It works by bringing devices to close proximity or simply having them touch each other. Even though the communication range of NFC is limited to just a few centimeters, eavesdropping, data modification and various other types of attacks are possible, since NFC alone does not ensure secure communication.

Example 2: The Android platform provides support for NFC. The following code creates a message that gets pushed to the other device within the range.

```
...  
public static final String TAG = "NfcActivity";  
private static final String DATA_SPLITTER = "__:DATA:__";  
private static final String MIME_TYPE = "application/my.applications.mimetype";  
...  
public NdefMessage createNdefMessage(NfcEvent event) {  
    TelephonyManager tm =  
(TelephonyManager)Context.getSystemService(Context.TELEPHONY_SERVICE);  
    String VERSION = tm.getDeviceSoftwareVersion();  
    String text = TAG + DATA_SPLITTER + VERSION;  
    NdefRecord record = new NdefRecord(NdefRecord.TNF_MIME_MEDIA,  
        MIME_TYPE.getBytes(), new byte[0], text.getBytes());  
    NdefRecord[] records = { record };  
    NdefMessage msg = new NdefMessage(records);  
    return msg;  
}  
...
```

NFC Data Exchange Format (NDEF) message contains typed data, a URI, or a custom application payload. If the message contains information about the application, such as its name, MIME type, or device software version, this information could be leaked to an eavesdropper. In Example 2, Fortify Static Code Analyzer reports a System Information Leak vulnerability on the return statement.

Recommendation

Write error messages with security in mind. In production environments, turn off detailed error information in favor of

brief messages. Restrict the generation and storage of detailed output that can help administrators and programmers diagnose problems. Debug traces can sometimes appear in non-obvious places (embedded in comments in the HTML for an error page, for example). Even brief error messages that do not reveal stack traces or database dumps can potentially aid an attacker. For example, an "Access Denied" message can reveal that a file or user exists on the system. If you are concerned about leaking system data via NFC on an Android device, you could do one of the following three things. Do not include system data in the messages pushed to other devices in range, encrypt the payload of the message, or establish a secure communication channel at a higher layer.

Unchecked Return Value (10 issues)

Abstract

Ignoring a method's return value can cause the program to overlook unexpected states and conditions.

Explanation

It is not uncommon for Java programmers to misunderstand `read()` and related methods that are part of many `java.io` classes. Most errors and unusual events in Java result in an exception being thrown. (This is one of the advantages that Java has over languages like C: Exceptions make it easier for programmers to think about what can go wrong.) But the stream and reader classes do not consider it unusual or exceptional if only a small amount of data becomes available. These classes simply add the small amount of data to the return buffer, and set the return value to the number of bytes or characters read. There is no guarantee that the amount of data returned is equal to the amount of data requested. This behavior makes it important for programmers to examine the return value from `read()` and other IO methods to ensure that they receive the amount of data they expect. **Example 1:** The following code loops through a set of users, reading a private data file for each user. The programmer assumes that the files are always exactly 1 kilobyte in size and therefore ignores the return value from `read()`. If an attacker can create a smaller file, the program will recycle the remainder of the data from the previous user and handle it as though it belongs to the attacker.

```
FileInputStream fis;
byte[] byteArray = new byte[1024];
for (Iterator i=users.iterator(); i.hasNext();) {
    String userName = (String) i.next();
    String pFileName = PFILE_ROOT + "/" + userName;
    FileInputStream fis = new FileInputStream(pFileName);
    fis.read(byteArray); // the file is always 1k bytes
    fis.close();
    processPFile(userName, byteArray);
}
```

Recommendation

```
FileInputStream fis;
byte[] byteArray = new byte[1024];
for (Iterator i=users.iterator(); i.hasNext();) {
    String userName = (String) i.next();
    String pFileName = PFILE_ROOT + "/" + userName;
    fis = new FileInputStream(pFileName);
    int bRead = 0;
    while (bRead < 1024) {
        int rd = fis.read(byteArray, bRead, 1024 - bRead);
        if (rd == -1) {
            throw new IOException("file is unusually small");
        }
        bRead += rd;
    }
    // could add check to see if file is too large here
    fis.close();
    processPFile(userName, byteArray);
}
```

Note: Because the fix for this problem is relatively complicated, you might be tempted to use a simpler approach, such as checking the size of the file before you begin reading. Such an approach would render the application vulnerable to a file system race condition, whereby an attacker could replace a well-formed file with a malicious file between the file size check and the call to read data from the file.

Unreleased Resource: Streams (11 issues)

Abstract

The program can potentially fail to release a system resource.

Explanation

The program can potentially fail to release a system resource. Resource leaks have at least two common causes: - Error conditions and other exceptional circumstances. - Confusion over which part of the program is responsible for releasing the resource. Most unreleased resource issues result in general software reliability problems. However, if an attacker can intentionally trigger a resource leak, the attacker may be able to launch a denial of service attack by depleting the resource pool. **Example 1:** The following method never closes the file handle it opens. The `finalize()` method for `FileInputStream` eventually calls `close()`, but there is no guarantee as to how long it will take before the `finalize()` method will be invoked. In a busy environment, this can result in the JVM using up all of its file handles.

```
private void processFile(String fName) throws FileNotFoundException,
IOException {
    FileInputStream fis = new FileInputStream(fName);
    int sz;
    byte[] byteArray = new byte[BLOCK_SIZE];
    while ((sz = fis.read(byteArray)) != -1) {
        processBytes(byteArray, sz);
    }
}
```

Recommendation

Use try-with-resources statements to ensure that any resource that implements the `AutoCloseable` interface is automatically closed at the end of the try block. **Example 2:** The following code uses try-with-resources statements to safely manage `FileInputStream` objects.

```
private void processFile(String fName) throws FileNotFoundException,
IOException {
    try (FileInputStream fis = new FileInputStream(fName)) {
        int sz;
        byte[] byteArray = new byte[BLOCK_SIZE];
        while ((sz = fis.read(byteArray)) != -1) {
            processBytes(byteArray, sz);
        }
    }
}
```

Example 3: For Kotlin, use the extension function `Closeable.use()` instead:

```
val fis = FileInputStream(fName)
fis.use {
    ...
}
```

If try-with-resources statements cannot be used, make sure to release the resources in a finally block. **Example 4:** The following code properly closes the `FileInputStream` object in a finally block.

```
public void processFile(String fName) throws FileNotFoundException,
IOException {
    FileInputStream fis;
    try {
        fis = new FileInputStream(fName);
        int sz;
        byte[] byteArray = new byte[BLOCK_SIZE];
```

```

        while ((sz = fis.read(byteArray)) != -1) {
            processBytes(byteArray, sz);
        }
    }
    finally {
        if (fis != null) {
            safeClose(fis);
        }
    }
}

public static void safeClose(FileInputStream fis) {
    if (fis != null) {
        try {
            fis.close();
        } catch (IOException e) {
            log(e);
        }
    }
}
}

```

This solution uses a helper function to log the exceptions that might occur when trying to close the statement. Presumably this helper function will be reused whenever a statement needs to be closed. Also, the `processFile` method does not initialize the `fis` object to `null`. Instead, it checks to ensure that `fis` is not `null` before calling `safeClose()`. Without the `null` check, the Java compiler reports that `fis` might not be initialized. This choice takes advantage of Java's ability to detect uninitialized variables. If `fis` is initialized to `null` in a more complex method, cases in which `fis` is used without being initialized will not be detected by the compiler.

Unsafe JNI (1 issue)

Abstract

Improper use of the Java Native Interface (JNI) can render Java applications vulnerable to security flaws in other languages.

Explanation

Unsafe JNI errors occur when a Java application uses JNI to call code written in another programming language.

Example 1: The following Java code defines a class named `Echo`. The class declares one native method that uses C to echo commands entered on the console back to the user.

```
class Echo {
    public native void runEcho();

    static {
        System.loadLibrary("echo");
    }

    public static void main(String[] args) {
        new Echo().runEcho();
    }
}
```

The following C code defines the native method implemented in the `Echo` class:

```
#include <jni.h>
#include "Echo.h" //the java class from <code>Example 1</code> compiled with
javah
#include <stdio.h>

JNIEXPORT void JNICALL
Java_Echo_runEcho(JNIEnv *env, jobject obj)
{
    char buf[64];
    gets(buf);
    printf(buf);
}
```

Because the example is implemented in Java, it may appear that it is immune to memory issues like buffer overflow vulnerabilities. Although Java does do a good job of making memory operations safe, this protection does not extend to vulnerabilities occurring in source code written in other languages that are accessed using the Java Native Interface. Despite the memory protections offered in Java, the C code in this example is vulnerable to a buffer overflow because it makes use of `gets()`, which does not perform any bounds checking on its input. The Sun Java(TM) Tutorial provides the following description of JNI [1]: The JNI framework lets your native method utilize Java objects in the same way that Java code uses these objects. A native method can create Java objects, including arrays and strings, and then inspect and use these objects to perform its tasks. A native method can also inspect and use objects created by Java application code. A native method can even update Java objects that it created or that were passed to it, and these updated objects are available to the Java application. Thus, both the native language side and the Java side of an application can create, update, and access Java objects and then share these objects between them. The vulnerability in Example 1 could easily be detected through a source code audit of the native method implementation. This may not be practical or possible depending on the availability of the C source code and the way the project is built, but in many cases it may suffice. However, the ability to share objects between Java and native methods expands the potential risk to much more insidious cases where improper data handling in Java may lead to unexpected vulnerabilities in native code or unsafe operations in native code corrupt data structures in Java. Vulnerabilities in native code accessed through a Java application are typically exploited in the same manner as they are in applications written in the native language. The only challenge to such an attack is for the attacker to identify that the Java application uses native code to perform certain operations. This can be accomplished in a variety of ways, including identifying specific behaviors

that are often implemented with native code or by exploiting a system information leak in the Java application that exposes its use of JNI [2].

Recommendation

Audit all source code comprising a given application, including native methods implemented in other languages. During audits, ensure that differences in bounds checking and other behavior between Java and native code are accounted for and handled correctly. In particular, verify that shared objects are handled correctly at all stages: before they are passed to native code, while they are manipulated by native code, and after they are returned to the Java application.

Weak Cryptographic Hash (1 issue)

Abstract

Weak cryptographic hashes cannot guarantee data integrity and should not be used in security-critical contexts.

Explanation

MD2, MD4, MD5, RIPEMD-160, and SHA-1 are popular cryptographic hash algorithms often used to verify the integrity of messages and other data. However, as recent cryptanalysis research has revealed fundamental weaknesses in these algorithms, they should no longer be used within security-critical contexts. Effective techniques for breaking MD and RIPEMD hashes are widely available, so those algorithms should not be relied upon for security. In the case of SHA-1, current techniques still require a significant amount of computational power and are more difficult to implement. However, attackers have found the Achilles' heel for the algorithm, and techniques for breaking it will likely lead to the discovery of even faster attacks.

Recommendation

Discontinue the use of MD2, MD4, MD5, RIPEMD-160, and SHA-1 for data-verification in security-critical contexts. Currently, SHA-224, SHA-256, SHA-384, SHA-512, and SHA-3 are good alternatives. However, these variants of the Secure Hash Algorithm have not been scrutinized as closely as SHA-1, so be mindful of future research that might impact the security of these algorithms.

XML Entity Expansion Injection (6 issues)

Abstract

Using XML parsers that are not configured to prevent or limit Document Type Definition (DTD) entity resolution can expose the parser to an XML Entity Expansion injection

Explanation

XML Entity Expansion injection also known as XML Bombs are Denial Of Service (DoS) attacks that benefit from valid and well-formed XML blocks that expand exponentially until they exhaust the server allocated resources. XML allows to define custom entities which act as string substitution macros. By nesting recurrent entity resolutions, an attacker may easily crash the server resources. The following XML document shows an example of an XML Bomb.

```
<?xml version="1.0"?>
<!DOCTYPE lolz [
  <!ENTITY lol "lol">
  <!ENTITY lol2 "&lol;&lol;&lol;&lol;&lol;&lol;&lol;&lol;&lol;&lol;">
  <!ENTITY lol3 "&lol2;&lol2;&lol2;&lol2;&lol2;&lol2;&lol2;&lol2;&lol2;&lol2;">
  <!ENTITY lol4 "&lol3;&lol3;&lol3;&lol3;&lol3;&lol3;&lol3;&lol3;&lol3;&lol3;">
  <!ENTITY lol5 "&lol4;&lol4;&lol4;&lol4;&lol4;&lol4;&lol4;&lol4;&lol4;&lol4;">
  <!ENTITY lol6 "&lol5;&lol5;&lol5;&lol5;&lol5;&lol5;&lol5;&lol5;&lol5;&lol5;">
  <!ENTITY lol7 "&lol6;&lol6;&lol6;&lol6;&lol6;&lol6;&lol6;&lol6;&lol6;&lol6;">
  <!ENTITY lol8 "&lol7;&lol7;&lol7;&lol7;&lol7;&lol7;&lol7;&lol7;&lol7;&lol7;">
  <!ENTITY lol9 "&lol8;&lol8;&lol8;&lol8;&lol8;&lol8;&lol8;&lol8;&lol8;&lol8;">
]>
<lolz>&lol9;</lolz>
```

This test could crash the server by expanding the small XML document into more than 3GB in memory.

Recommendation

Always configure an XML parser securely so that it does not allow document type definition (DTD) custom entities as part of an incoming XML document. To avoid XML Entity Expansion injection the "secure-processing" property should be set for an XML factory, parser or reader:

```
factory.setFeature("http://javax.xml.XMLConstants/feature/secure-processing",
true);
```

In JAXP 1.3 and earlier versions, when the secure processing feature is on, default limitations are set for DOM and SAX parsers. These limits are:

```
entityExpansionLimit = 64,000
elementAttributeLimit = 10,000
```

Since JAXP 1.4, the secure processing feature is turned on by default. In addition to the preceding limits, a new maxOccur limit is added to the validating parser. The limit is:

```
maxOccur = 5,000
```

If inline DOCTYPE declaration is not needed, it can be completely disabled with the following property:

```
factory.setFeature("http://apache.org/xml/features/disallow-doctype-decl",
true);
```

To protect a TransformerFactory, the following feature should be set:

```
TransformerFactory transFact = TransformerFactory.newInstance();
transFact.setFeature(XMLConstants.FEATURE_SECURE_PROCESSING, true);
Transformer trans = transFact.newTransformer(xsltSource);
trans.transform(xmlSource, result);
```

Alternatively, it is possible to use a securely configured XMLReader to set the transformation sources:

```
XMLReader reader = XMLReaderFactory.createXMLReader();
reader.setFeature("http://apache.org/xml/features/disallow-doctype-decl",
true);
Source xmlSource = new SAXSource(reader, new InputSource(new
FileInputStream(xmlFile)));
```

```
Source xsltSource = new SAXSource(reader, new InputSource(new
FileInputStream(xsltFile)));
Result result = new StreamResult(System.out);
TransformerFactory transFact = TransformerFactory.newInstance();
Transformer trans = transFact.newTransformer(xsltSource);
trans.transform(xmlSource, result);
```

XML External Entity Injection (6 issues)

Abstract

Using XML parsers that are not configured to prevent or limit external entities resolution can expose the parser to an XML External Entities attack

Explanation

XML External Entities attacks benefit from an XML feature to build documents dynamically at the time of processing. An XML entity allows inclusion of data dynamically from a given resource. External entities allow an XML document to include data from an external URI. Unless configured to do otherwise, external entities force the XML parser to access the resource specified by the URI, e.g., a file on the local machine or on a remote system. This behavior exposes the application to XML External Entity (XXE) attacks, which can be used to perform denial of service of the local system, gain unauthorized access to files on the local machine, scan remote machines, and perform denial of service of remote systems. The following XML document shows an example of an XXE attack.

```
<?xml version="1.0" encoding="ISO-8859-1"?>
<!DOCTYPE foo [
  <!ELEMENT foo ANY >
  <!ENTITY xxe SYSTEM "file:///dev/random" >]><foo>&xxe;</foo>
```

This example could crash the server (on a UNIX system), if the XML parser attempts to substitute the entity with the contents of the /dev/random file.

Recommendation

Always configure an XML parser securely so that it does not allow external entities as part of an incoming XML document. To avoid XXE injections the following properties should be set for an XML factory, parser or reader:

```
factory.setFeature("http://xml.org/sax/features/external-general-entities",
false);
factory.setFeature("http://xml.org/sax/features/external-parameter-entities",
false);
```

If inline DOCTYPE declaration is not needed, it can be completely disabled with the following property:

```
factory.setFeature("http://apache.org/xml/features/disallow-doctype-decl",
true);
```

To protect a TransformerFactory, the following attribute should be set:

```
TransformerFactory transFact = TransformerFactory.newInstance();
transFact.setAttribute(XMLConstants.ACCESS_EXTERNAL_DTD, "");
Transformer trans = transFact.newTransformer(xsltSource);
trans.transform(xmlSource, result);
```

Alternatively, it is possible to use a securely configured XMLReader to set the transformation sources:

```
XMLReader reader = XMLReaderFactory.createXMLReader();
reader.setFeature("http://xml.org/sax/features/external-general-entities",
false);
reader.setFeature("http://xml.org/sax/features/external-parameter-entities",
false);
Source xmlSource = new SAXSource(reader, new InputSource(new
FileInputStream(xmlFile)));
Source xsltSource = new SAXSource(reader, new InputSource(new
FileInputStream(xsltFile)));
Result result = new StreamResult(System.out);
TransformerFactory transFact = TransformerFactory.newInstance();
Transformer trans = transFact.newTransformer(xsltSource);
trans.transform(xmlSource, result);
```

```

XML External Entity Injection	High
Package: com.atakmap.android.helloworld	
sdk/ATAK-CIV-5.4.0.18-SDK/samples/helloworld/app/src/main/java/com/atakmap/android/helloworld/HelloWorldMapComponent.java, line 701 (XML External Entity Injection)	High

Issue Details

Kingdom: Input Validation and Representation
Scan Engine: SCA (Control Flow)

Sink Details

Sink: factory.newTransformer() : XML document parsed allowing external entity resolution
Enclosing Method: BuildExternalMunitionsQuery()
File: sdk/ATAK-CIV-5.4.0.18-SDK/samples/helloworld/app/src/main/java/com/atakmap/android/helloworld/HelloWorldMapComponent.java:701
Taint Flags:

```

698 doc.appendChild(rootEl);
699
700 TransformerFactory factory = TransformerFactory.newInstance();
701 Transformer transformer = factory.newTransformer();
702
703 DOMSource domSource = new DOMSource(doc.getDocumentElement());
704 OutputStream output = new ByteArrayOutputStream();

```

Package: com.atakmap.android.sampledetailtester	
sdk/ATAK-CIV-5.4.0.18-SDK/samples/sampledetailtester/app/src/main/java/com/atakmap/android/sampledetailtester/StudentMapComponent.java, line 118 (XML External Entity Injection)	High

Issue Details

Kingdom: Input Validation and Representation
Scan Engine: SCA (Control Flow)

Sink Details

Sink: tf.newTransformer() : XML document parsed allowing external entity resolution
Enclosing Method: decode()
File: sdk/ATAK-CIV-5.4.0.18-SDK/samples/sampledetailtester/app/src/main/java/com/atakmap/android/sampledetailtester/StudentMapComponent.java:118
